Yu Zhang (yuzhang@ustc.edu.cn)

University of Science and Technology of China

Thanks Prof. Adve for providing CS426 course materials!

What is a Compiler?

Compiler \equiv A program that translates code in one language (source code) to code in another language (target code).

Usually, target code is semantically equivalent to source code, but not always!

Examples

- C++ to Sparc assembly
- C++ to C (some C++ compilers work this way)
- Java to JVM bytecode
- High Performance Fortran (HPF: a parallel Fortran language) to Fortran: a parallelizing compiler
- C to C (or any language to itself):
Why? Make code faster, or smaller, or instrument for performance ...

Uses of Compiler Technology

- **Code generation:** To translate a program in a high-level language to machine code for a particular processor
- **Optimization:** Improve program performance for a given target machine
- **Text formatters:** translate TeX to dvi, dvi to postscript, etc.
- **Interpreters:** “on-the-fly” translation of code, e.g., Java, Perl, csh, Postscript
- **Automatic parallelization or vectorization**
- **Debugging aids:** e.g., purify for debugging memory access errors
- **Performance instrumentation:** e.g., -pg option of cc or gcc for profiling
- **Security:** JavaVM uses compiler analysis to prove safety of Java code
- **Many more cool uses!** Power management, code compression, fast simulation of architectures, transparent fault-tolerance, global distributed computing, ...

Key: Ability to extract properties of a program (analysis), and optionally transform it (synthesis)

A Code Optimization Example

What machine-independent optimizations are applicable to the following C example? When are they safe?

```

1  /* A, B, C are double arrays; X, Y are double scalars; rest are int scalars.
2  int main(int argc, char** argv) {
3      ... /* Declare and initialize variables. */
4      X = ...;
5      N = 1; i = 1;
6      while (i <= 100) {
7          j = i * 4;
8          N = j * N;
9          Y = X * 2.0;
10         A[i] = X * 4.0;
11         B[j] = Y * N;
12         C[j] = N * Y * C[j];
13         i = i + 1;
14     }
15     printArray(B, 400);
16     printArray(C, 400);
17 }
```

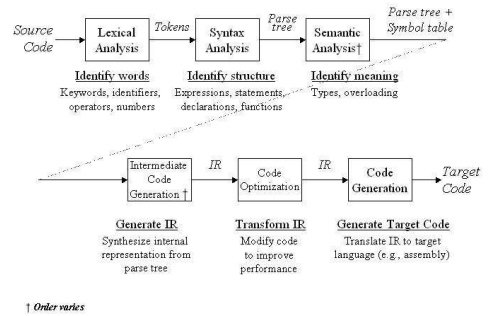

A Code Optimization Example: Result

```

1 X = ...
2 N = 1;
3 j = 4;
4                                     // Induction Variable Substitution (SUBST),
                                     // Strength Reduction
5 Y = X * 2.0;
6 while (j <= 400) {
7                                     // Loop-Invariant Code Motion (LICM)
7                                     // Linear Function Test Replacement (LFTR)
7                                     // Dead Code Elimination (DCE) for i * 4
8     N = j * N;
9                                     // DCE of A, since A not aliased to B or C
10    tmp = Y * N;
11    B[j] = tmp;
12    C[j] = tmp * C[j]; // Common Subexpression Elimination (CSE)
13    j = j + 4;         // Induction Variable Substitution,
14                     // Strength Reduction
15 }
16 printArray(B, 400);
17 printArray(C, 400);

```

General Structure of a Compiler

Topical Outline

1. The structure of a compiler
2. Intermediate representations
3. Runtime storage management (excluding garbage collection)
4. Intermediate code generation
5. Code Optimization
 - Peephole optimizations
 - Control flow graphs and analysis
 - Static Single Assignment (SSA) form
 - Introduction to iterative dataflow analysis
 - SSA and iterative dataflow optimizations
6. Global Register allocation
7. Global Instruction Scheduling (if time permits)

Programming Projects

An Optimizing Compiler for COOL using C++

Source Language: COOL

- Object-oriented language similar to Java
- But small and very well-defined: syntax *and* semantics

Target Language: LLVM Virtual Instruction Set

- *Both* intermediate representation *and* assembly language
- Designed for effective language-independent optimization

Programming Projects (Cont.)

Project phases

- MP1: *Scanning and Parsing*: COOL to Abstract Syntax Tree (AST)
 - MP1.1: Preparation; MP1.2: Scanner; MP1.3: Parser; MP1.4: Parser(AST)
- MP2: *Intermediate code gen., Part 1*: AST to LLVM, local expressions only
- MP3: *Intermediate code gen., Part 2*: AST to LLVM, all of COOL
- MP4: *Dataflow (SSA) Optimizations*: ADCE, LICM

Unit Project (Teams of 2): Write a graph-coloring register allocator for LLVM on X86

MP1.1 Getting Started on the Programming Projects

1. Print and read the COOL manual, Chapters 1-11 (through syntax) at least. The manual is on the class web site under the Resources/ link.
2. Download and read the COOL examples from the file cool-examples.tar.gz. Write several COOL programs to get familiar with the syntax.
3. *DON'T* download or install LLVM! We will release a reduced version for your use in this class.

Getting The Most Out Of AnyClass

“Education is what survives when what has been learned has been forgotten.” –B. F. Skinner, *New Scientist*, May 21, 1964.

Get the big picture:

Why are we doing this? Why is it important?

Understand the basic principles:

If you know how to apply them, you can work out the details

Learn why things work a certain way:

Automatic vs. manual, elegant vs. ad hoc,
solved problem vs. open

Think about the cost-benefit trade-offs:

Performance vs. correctness, compile-time vs. payoff

Getting The Most Out Of This Class

*“Sir, I can give you an explanation
but not an understanding!”*

–British parliamentarian.

- Do the exercises in class; read the text and notes

- Start the assignment the day it's handed out, not the day it's due

- Pay attention to the discussions

- Ask questions, and participate
